(54) Multi-media integrated message arrangement.

(57) Voice, facsimile, and electronic mail messaging is integrated in a system that converts e-mail messages into voice-and-fax messages. An e-mail message (400) is parsed into voiceable, prose, segments (403) and non-voiceable, non-prose, segments (404). Prose segments are converted into voice message segments (503) via text-to-speech facilities. Each non-prose segment is converted into a fax segment (504). Voice pointers (505) to fax segments are inserted into the voice message, in places corresponding to the non-prose segments in the e-mail message. The voice file (500) and fax file (510) are then stored for subsequent delivery of the message as an integrated voice-and-fax message. Conversion of integrated voice-and-fax messages into e-mail messages is likewise envisioned.

FIG. 4

EP 0 615 368 A2

Technical Field

This invention relates generally to integrated message systems, and specifically to voice-and-fax message systems and electronic mail systems.

Background of the Invention

Multi-media messaging involves integrating discrete messages or individual message components of different media, e.g., voice, text, video, and the ability to deliver the integrated messages through a single universal mailbox.

The integration of voice and facsimile (fax) messages is well known in the art. For example, U.S. Patent No. 5,008,926, discloses an integrated voice-and-facsimile store-and-forward message system that provides for the sending, storage, and delivery of voice messages, fax messages, fax messages annotated with voice messages, and voice messages annotated with fax messages. The disclosed system additionally provides for display of fax messages on terminal screens, and the conversion of fax printed text messages into voice messages via text-to-speech conversion facilities.

Electronic mail, or e-mail, systems are also well known in the art. They provide for the sending, storage, and delivery between computer terminals of displayable data --text and/or graphics-- messages.

Integration of e-mail systems with voice-and-fax message systems is highly desirable. For example, it is becoming common for salesmen to work out of "mobile offices" --their cars-- which are equipped normally with telephones, often with fax machines, but generally not with data terminals, yet the salesmen would like to have the capability of receiving in their mobile offices messages sent to them in any form --voice, fax, or e-mail. The integration of fax and e-mail messaging is readily accomplished through conversion of e-mail messages into fax messages for delivery to their recipients. But while fax machines are more likely to be available to mobile recipients of the messages than data terminals, they are not as readily available as telephones. Therefore, it is often preferable to instead accomplish the integration of voice and e-mail messaging through conversion of e-mail messages into voice messages for delivery to their recipients. This type of conversion is also readily accomplished if the e-mail messages constitute text only.

A problem arises, however, when e-mail messages constitute information other than text --such as diagrams, charts, special symbols, computer code fragments, pictures, etc.-- which is not suitable for conversion into a voice message. Attempts to convert such data message segments into speech result in unintelligible garble. This may be avoided by simply identifying and discarding the non-voiceable data message segments, but this results in the delivery of

an incomplete message to the recipient --an unacceptable result.

Summary of the Invention

5

This invention is directed to solving these and other problems and disadvantages of the prior art. Generally according to the invention, data messaging, such as e-mail messaging, is integrated with audio-and-image messaging, such as voice-and-fax messaging, by converting voiceable segments of a data message into voice message segments, converting non-voiceable segments of the data message into image message segments, and substituting in the voice message voiced pointers to the image message segments in place of the non-voiceable segments. Alternatively, the transformation of the message from one media to another may be done in the reverse direction.

10

According to specific principles of the invention, segments of information (for example, of a received message) represented in a first medium (for example, e-mail) which can be represented in a second medium (for example, voice) are identified, representation of the identified segments is converted from the first medium into the second medium, representation of other segments of the obtained information is converted from the first medium into a third medium (for example, fax) and then pointers represented in the second medium and pointing to the segments represented in the third medium are interspersed among the segments represented in the second medium. The information represented in the second and third media may then be substituted for the information represented in the first medium.

20

The conversion of the information from one set of media to another allows the information to be delivered and presented to a user in a form selected by, and most suitable to, the user. Yet, the multi-media

25

form of the message ensures that none of the informational content of the message need be discarded during the conversion process. Thus, for example, a traveling sales representative is able to receive the voice portion of the converted e-mail message on his

30

or her mobile telephone and decide from the contents of the voice portion whether to go to the effort of printing the associated fax component of the message. If the recipient decides to receive the entire message, he or she is able to receive the entire e-mail message

35

as an integrated voice-and-fax message on his or her mobile telephone and fax without loss of any of the information carried by the e-mail message. Furthermore, the pointers used in the multi-media message

40

to point from one medium to the other ensure that the recipient can follow the logical flow of the original message in the multi-media message, and can receive all the information contained in the original message in the proper order.

Preferably, header information of a received e-mail message is converted for delivery to a recipient into a voice header. This allows the recipient to examine and browse through headers of integrated voice-and-fax messages in the same manner as he or she does with headers of conventional voice messages. Further preferably, certain white-space segments of the e-mail message which carry no user information, are discarded during the conversion process. This increases the efficiency and compactness of the resulting integrated voice-and-fax message.

These and other advantages and features of the invention will become more apparent from the following description of an illustrative embodiment of the invention considered together with the drawing.

Brief Description of the Drawing

FIG. 1 is a block diagram of a multi-media integrated message system embodying an illustrative example of the invention; FIG. 2 is a flow diagram of message storing and delivery functions of an integrated voice-and-facsimile store-and-forward system of the multi-media integrated message system of FIG. 1; FIG. 3 is a flow diagram of an e-mail message to integrated voice-and-facsimile message conversion function of an e-mail system of the multi-media integrated message system of FIG. 1; and FIG. 4 is a symbolic representation of the e-mail message to integrated voice-and-facsimile message conversion performed by the function of FIG. 3.

Detailed Description

FIG. 1 shows an illustrative telecommunications system. It comprises telephone terminals 29 and fax terminals 30 connected by a private branch exchange switch (PBX) 24 to a message system 1000. Message system 1000 stores voice and fax messages in a mass storage 12, such as a disk, operating under control of a controller 10. Terminals 29 and 30 access message system 1000 through PBX 24 over phone lines 1004 and a voice/data interface 34 that interfaces phone lines 1004 to the internal circuits and functions of message system 1000, to store the messages in system 1000 and to retrieve the messages from system 1000. Message system 1000 is illustratively the AT&T Ovation multimedia communication system, or an AT&T voice-mail system of the type disclosed in EP-A-0554980 or in EP-A-0581484, this application, which systems are further adapted to store both voice and fax messages. Alternatively, portion 1 of the system of FIG. 1 which includes terminals 29 and 30, PBX 24, and message system 1000, is illustratively the integrated voice-and-facsimile store-and-forward system disclosed in U.S. Patent No.

5,008,926.

Whilst the operation of message system 1000 is described in the above-referenced patent, a brief overview of its functionality relevant hereto is presented here and in FIG. 2 for completeness of description. As mentioned above, message system 1000 operates under the guidance of a control 10. Control 10 is illustratively a general-purpose processor operating under control of programs 1006 stored in its memory. Execution of programs 1006 implements the store-and-forward messaging functionality flowcharted in FIG. 2.

In response to receipt of a call, at step 200 of FIG. 2, control 10 determines from caller input whether or not this is a message storage request, at step 202. If so, control 10 identifies from the caller's input the caller/message sender and the intended message recipient, at step 204, and the message medium or media, at step 206. In this example, the media may be voice, fax, or voice-plus-fax, though other media, such as video, may also be allowed. Control 10 then forms a message header that includes information such as the sender's identification, date and time of receipt of the message, etc., and sets media I.D. flags in the header to indicate the identified message media, at step 208. Control 10 then receives the segment, if any, of the message which is in the voice medium, at step 210, stores the received segment in a file in mass storage 12, at step 212, and sets a voice file pointer in the message header to point to the stored file, at step 214. Control 10 performs the same functions for the segment, if any, of the message which is in the fax medium, at steps 214-220. Control 10 then stores the header in the intended message recipient's universal mailbox in mass storage 12, at step 222, and returns to step 202 to determine if the caller has further requests.

If the caller's request is not to store a message, as determined at step 202, control 10 determines from the caller's input whether this is a message retrieval request, at step 230. If not, control 10 continues its operation with other conventional operations, not relevant hereto, at step 250. If so, control 10 identifies the caller, at step 232, and then retrieves stored message headers from the caller's universal mailbox and sends them to the caller, at step 234. Control 10 then determines from the caller's further input whether the caller has selected a message for retrieval, at step 236. If not, control 10 returns to step 202; if so, control 10 examines the media I.D. flags of the header of the selected message to determine the message's media, at step 238. Control 10 then retrieves the message segments that are in the identified media using the file pointers of the message header, and sends the message segments to the caller, at steps 240-242. Control 10 then returns to step 202.

As shown in FIG. 1, message system 1000 is connected by a local area network (LAN) 1001 to an elec-

tronic mail (e-mail) network 1003. LAN 1001 is interfaced to the internal circuits and functions of message system 1000 by a LAN interface 84, in a conventional manner such as is disclosed in the above-referenced patent no. 5,008,926.

E-mail network 1003 is a conventional network, comprising a plurality of communicatively interconnected computers including the e-mail computer 1002. Computer 1002 couples data terminals 28 to network 1003, by means of which users can send and retrieve e-mail messages in a conventional manner.

According to the invention, however, an e-mail user who is also served by system portion 1 has the choice of receiving e-mail messages either in the conventional manner, or as integrated voice-and/or-fax messages through portion 1. The user's choice is programmed into the user's e-mail profile stored by computer 1002. If the user has chosen to receive e-mail messages through portion 1, computer 1002 examines an e-mail message received for that user to determine which segments thereof can be converted into a voice message via text-to-speech functions, and which segments thereof are not amenable to this conversion. The convertible segments are converted into a voice message, and the nonconvertible segments are converted into a fax message. Voice references pointing to the fax message are inserted into the voice message in place of the nonconvertible segments. The voice and fax messages are then delivered to message system 1000 for storage and subsequent delivery to the recipient in the conventional integrated voice-and-fax messaging manner.

According to the invention, in order to integrate e-mail messages into the integrated voice-and-facsimile store-and-forward system which forms portion 1, computer 1002 executes programs 1005 stored in its memory that implement the functionality flowcharted in FIG. 3.

In response to receiving an e-mail message for a user served by it, at step 300 of FIG. 3, computer 1002 identifies the recipient in a conventional manner, at step 302, and then examines the identified recipient's stored user profile, at step 304, to determine, at step 306, whether the user wishes to have e-mail messages delivered in the conventional manner via terminal 28 or as integrated voice-and-fax messages via phone and fax terminals 29 and 30 by way of message system 1000. If conventional delivery is indicated, computer 1002 proceeds to handle the received message in the conventional e-mail manner, at step 310.

If integrated voice-and-fax delivery is indicated, computer 1002 parses the message, at step 312, to separate it into segments classified by type. This is illustrated by the logical conversion diagram of FIG. 4. An e-mail message 400 is an ASCII-format file with a predefined header 401 followed by a sequence of lines of ASCII characters. Besides the header, the following types of segment lines are defined: white-

space 402, consisting of a blank line; prose 403, consisting of natural language or numerals interspersed with standard punctuation; and non-prose 404, which is anything else. Computer 1002 classifies each line of the message into one of the above four types. The header is identified by sentinels predefined for this particular e-mail system (e.g., DATE:, FROM:, SUBJECT:). Whitespace 402 is identified by a lone newline or linefeed character. Prose 403 lines are identified by strings of ASCII characters forming words, numbers, and conventional (natural-language) punctuation. Any lines not identified as header 401, whitespace 402, or prose 403 are classified as non-prose 404. These are, for example, lines containing graphics symbols, nonstandard characters (e.g., bar, angle bracket, ampersand, numerical signs, etc.), non-standard punctuation or standard punctuation used in non-standard manner (e.g., a sequence of colons or semicolons), a string that is a mix of letters and numerals, etc.

Having classified each line of the message according to type and thus separated the message into segments 401-404, computer 1002 now interprets the information of header segment 401 to create, via conventional text-to-speech technology, a voice message header 501 conveying that information, at step 314 of FIG. 3. Computer 1002 then converts prose segments 403 into voice message segments 503, again using text-to-speech technology, at step 316. Computer 1002 ignores and discards whitespace segments 402 that are interspersed among prose segments 403, at step 318. Computer 1002 also converts each non-prose segment 404 into a fax segment 504 (such as a fax page), at step 319. Illustratively, computer 1002 does this by first using the ASCII form of the non-prose segment to generate a PostScript file via a utility such as Nroff or Troff, and then converting the PostScript file into standard G3 fax format. Alternatively, the conversion from ASCII to G3 fax bitmap is performed directly. Computer 1002 retains, as part of the fax, whitespace segments 402 that are surrounded by non-prose segments 404.

Next, computer 1002 inserts into the voice message, at the places that were occupied in e-mail message 400 by the non-prose segments 404, voice pointers 505 to the appropriate fax segments 504, at step 320. An example of a voice pointer 505 is "Refer to attached document section x". Computer 1002 then stores the voice message with the voice pointers into a voice file 500 in its memory, and stores the fax segments into a fax file 510 in its memory, at step 322. E-mail message 400 has now been converted into the format of integrated voice-and-fax messages dealt with by system 1000, and computer 1002 transfers the voice file 500 and fax file 510 of the integrated voice-and-fax message 600 over LAN 1001 to message system 1000, at step 324, and ends its operation, at step 326. Illustratively, the transfer over LAN

is performed by means of an applications programmer interface (API) program communicating by means of a utility such as transfer control protocol/internet protocol (TCP/IP) remote procedure call (RPC) server function in LAN interface 84. Controller 10 of system 1000 treats LAN 1001 as a caller and stores the message 600 in the manner shown in FIG. 2. Then, upon demand, controller 10 presents message 600 as an integrated voice-and-fax message to the recipient user, also in the manner shown in FIG. 2.

Of course, various changes and modifications to the illustrative embodiment described above will be apparent to those skilled in the art. For example, the conversion of the e-mail message into an integrated voice-and-fax message may be performed at the message originator's computer, in a central conversion host computer in the e-mail system, or in message system 1000. Also, the conversion need not be limited to voice and fax media, but may involve other media such as video. Furthermore, the process may be reversed, whereby received integrated voice-and-fax messages are converted into e-mail messages for delivery. Further still, features may be added to improve the coherence and appearance of the output. For example, sentinels may be included in the e-mail message to direct which components of the e-mail message are to be converted to fax irrespective of whether they are non-prose or prose components. Or, limits may be set on the minimum line size of prose segments that will be converted to voice format; smaller prose segments interspersed with non-prose segments will then be converted to fax.

Claims

1. A method of media conversion, CHARACTERISED BY the steps of:

- identifying (312) segments (403) of obtained information represented in a first medium in which the information is presentable to a person and which can be represented in a second medium in which the information is presentable to a person;
- converting (316) representation of the identified segments from the first medium into the second medium;
- converting (319) representation of other segments (404) of the obtained information from the first medium into a third medium in which the information is presentable to a person; and
- interspersing (320) pointers (505), represented in the second medium and pointing to the segments represented in the third medium, among the segments represented in the second medium.

- 2. The method of claim 1 CHARACTERISED IN THAT**
 - the step of identifying comprises the steps of
 - obtaining (300) an e-mail message (400), and
 - identifying (312) segments (403) of the obtained e-mail message that can be converted into voice message segments;
 - the first step of converting comprises the step of
 - converting (316) the identified segments into voice message segments (503);
 - the second step of converting comprises the step of
 - converting (319) other segments (404) of the e-mail message into fax message segments (504); and
 - the step of interspersing comprises the steps of
 - interspersing (320) voice pointers (505) to the fax message segments among the voice message segments, and
 - delivering (324) the received message as an integrated voice-and-fax message (600) comprising the fax message segments and the voice message segments interspersed with the voice pointers.
- 3. The method of claim 2 CHARACTERISED IN THAT**
 - the step of converting other segments comprises the steps of:
 - selecting (312) other segments of the e-mail message that are not to be discarded;
 - converting (319) the selected segments into the fax message segments; and
 - discarding (318) segments (402) of the obtained message other than the identified and the selected segments.
- 4. The method of claim 1 CHARACTERISED IN THAT**
 - the step of identifying comprises the steps of
 - receiving (300) an e-mail message, and
 - parsing (312) the received message into header (401), whitespace (402), prose (403), and non-prose (404) segments;
 - the first step of converting comprises the steps of
 - converting (314) the header segment into a voice header segment (501), and
 - converting (316) the prose segments into voice message segments (503);
 - the second step of converting comprises the step of
 - converting (319) the non-prose segments

- into fax message segments (504); and
the step of interspersing comprises the
steps of
inserting (320) among the voice message
segments, at places occupied in the received
e-mail message by the non-prose segments, voice
pointers (505) to the fax message segments, and
delivering (324) the received message to a
recipient as an integrated voice-and-fax message
(600) comprising a voice message that includes
the voice header segments, the voice message
segments, and the inserted voice pointers, and
further comprising a fax message that includes
the fax segments.
- 5
5. The method of claim 4 CHARACTERISED BY the
further step of:
discarding (318) the whitespace segments
(402) except those that are surrounded by the
non-prose segments.
- 10
6. A media-conversion arrangement CHARACTER-
ISED BY
means (1002,1005:312) for identifying
segments (403) of obtained information repre-
sented in a first medium in which the information
is presentable to a person and which can be re-
presented in a second medium in which the infor-
mation is presentable to a person;
processor means (1002,1005:316) for
converting representation of the identified seg-
ments from the first medium into the second me-
dium;
processor means (1002,1005:319) for
converting representation of other segments
(404) of the obtained information from the first
medium into a third medium in which the informa-
tion is presentable to a person; and
means (1002,1005:320) for interspersing
pointers (505), represented in the second me-
dium and pointing to the segments represented in
the third medium, among the segments repre-
sented in the second medium.
- 15
7. The arrangement of claim 6 CHARACTERISED
IN THAT
the identifying means comprise
means (1002,1005:300) for obtaining an e-
mail message, and
means (1002,1005:312) for identifying
segments (403) of the obtained e-mail message
that can be converted into voice message seg-
ments;
the first processor means comprise
means (1002,1005:316) for converting the
identified segments into voice message seg-
ments (503);
the second processor means comprise
- 20
- means (1002,1005:319) for conv rting
other segments (401) of the e-mail message into
fax message s gments (504); and
the interspersing m ans comprise
means (1002,1005:320) for interspersing
voice pointers (505) to the fax message seg-
ments among the voice message segments, and
means (1002,1005:324) for delivering the
received message as an integrated voice-and-fax
message (600) comprising the fax message seg-
ments and the voice message segments inter-
spersed with the voice pointers.
- 25
8. The arrangement of claim 7 CHARACTERISED
IN THAT
the means for converting other segments
comprise:
means (1002,1005:312) for selecting
other segments of the e-mail message that are
not to be discarded;
means (1002,1005:319) for converting the
selected segments into the fax message seg-
ments; and
means (1002,1005:318) for discarding
segments (402) of the obtained message other
than the identified and the selected segments.
- 30
9. The arrangement of claim 6 CHARACTERISED
IN THAT
the identifying means comprise
means (1002,1005:300) for receiving an e-
mail message, and
processing means (1002,1005:312) for
parsing the received message into header (401),
whitespace (402), prose (403), and non-prose
(404) segments;
the first processor means comprise
processing means (1002,1005:314) for
converting the header segment into a voice head-
er segment (501), and
processing means (1002,1005:316) for
converting the prose segments into voice mes-
sage segments (503);
the second processor means comprise
processing means (1002,1005:319) for
converting the non-prose segments into fax mes-
sage segments (504); and
the interspersing means comprise
means (1002,1005:320) for inserting
among the voice message segments, at places
occupied in the received e-mail message by the
non-prose segments, voice pointers (505) to the
fax message segments, and
means (1002,1005:324) for delivering the
received message to a recipient as an integrated
voice-and-fax message (600) comprising a voice
message that includes the voice header seg-
ments, the voice message segments, and the in-
- 35

(54) Multi-media integrated message arrangement.

(57) Voice, facsimile, and electronic mail messaging is integrated in a system that converts e-mail messages into voice-and-fax messages. An e-mail message (400) is parsed into voiceable, prose, segments (403) and non-voiceable, non-prose, segments (404). Prose segments are converted into voice message segments (503) via text-to-speech facilities. Each non-prose segment is converted into a fax segment (504). Voice pointers (505) to fax segments are inserted into the voice message, in places corresponding to the non-prose segments in the e-mail message. The voice file (500) and fax file (510) are then stored for subsequent delivery of the message as an integrated voice-and-fax message. Conversion of integrated voice-and-fax messages into e-mail messages is likewise envisioned.
